The goal is to make a simple Go board that allows two players to take turns placing stones.

How the board works

The board is coded to have 9 rows and 9 columns filled with dots. I will use lists and inputs from the user to keep track of the spots on the board. Every spot starts as a period and then gets replaced with either empty or full circles. The rows on the board are labeled A through I, while the columns on the board are numbered 1 through 9. Black stones will be indicated with chr(9675) and white stones indicated with chr(9679).

How to enter a move

The board should always appear and show the dots before and after the user inputs a stone. When the board appears, type a row letter and a column letter, like A1. Type STOP when you want to end the game. If you pick a spot that has already been taken, the game will tell you to try again. It will be Black's turn first then white, and then switch after every move.

Algorithm

1. Make a 9 × 9 board and fill every spot with a period.
2. Set the first player to black.
3. Show the board before the user inputs a move.
4. Ask the user to enter a location or tell them to type STOP.
5. If the player stops, stop the program/game.
6. If not, make sure the user entered a valid location from A to I and a number from 1 to 9. If they do not then have them go again.
7. Turn that matching row and matching column into the correlating players stone using the list of lists.
8. If the spot already has a stone, tell the player to pick again.
9. If the spot is empty then put that stone there.
10. Switch to the other player and return to step 3 to redo, until the player types STOP.

How to run it

Open the go_moves.py code in VS code. Open the terminal and hit the "Run Python File" in the top right corner. Enter a valid location with a letter from A to I and a number from 1 to 9. Once you are finished with the game type STOP.

The program is designed to only run the Go game by placing stones and switching turns. It will not check other rules like who wins.
